## 1 Scott domain model of PCF

Interpretation of general recursion and if-zero test

Interpretation of types and contexts

**Definition 1.** Every type  $\sigma$  in **PCF** associates with a domain  $D_\sigma$  as follows:

1.  $\llbracket \mathbf{nat} \rrbracket := \mathbb{N}_\perp$ , and
2.  $\llbracket \tau \rightarrow \sigma \rrbracket := \llbracket \sigma \rrbracket^{\llbracket \tau \rrbracket}$ .

**Definition 2.** For each context  $\Gamma = x_1 : \sigma_1, x_2 : \sigma_2, \dots, x_n : \sigma_n$ , the associated domain is defined as

$$\llbracket \Gamma \rrbracket := \llbracket \sigma_1 \rrbracket \times \llbracket \sigma_2 \rrbracket \times \dots \times \llbracket \sigma_n \rrbracket$$

and the associated domain of the empty context is  $1 = \{\perp\}$ .

Every judgement of this form  $\Gamma \vdash M : \tau$  will be interpreted as a function

$$\llbracket \Gamma \vdash M : \tau \rrbracket : \llbracket \Gamma \rrbracket \rightarrow \llbracket \tau \rrbracket.$$

Interpretation of simply type lambda calculus and natural numbers

$$\llbracket \Gamma \vdash Yx. M : \sigma \rrbracket := \mu \circ \Lambda[\Gamma, x : \sigma \vdash M : \sigma]$$

$$\begin{aligned} & \llbracket \Gamma \vdash \mathbf{ifz}(M; M_0; M_1) : \tau \rrbracket \\ & := \mathbf{ifz}_\tau \circ \langle \llbracket \Gamma \vdash M : \mathbf{nat} \rrbracket, \llbracket \Gamma \vdash M_0 : \tau \rrbracket, \Lambda[\Gamma, x : \mathbf{nat} \vdash M_1 : \tau] \rangle \end{aligned}$$

where  $S$  and  $\mathbf{ifz}_\tau$  are defined by

$$S(n) := \begin{cases} \perp & \text{if } d = \perp \\ n + 1 & \text{otherwise.} \end{cases}$$

$$\mathbf{ifz}_\tau(n, x, f) := \begin{cases} \perp & \text{if } n = \perp, \\ x & \text{if } n = 0, \\ f(m) & \text{if } n = m + 1. \end{cases}$$

In particular, every program  $M : \tau$  associates with a function from 1 to  $\llbracket \tau \rrbracket$ , and thus determines a unique element  $\llbracket M \rrbracket(*)$  of  $\llbracket \tau \rrbracket$ .

**Convention**

For brevity, we write  $\llbracket M \rrbracket$  instead of  $\llbracket \vdash M : \tau \rrbracket$  for every program  $M$  of type  $\tau$

**Theorem 3.** For every judgement  $\Gamma \vdash M : \tau$ , the associated function

$$\llbracket \Gamma \vdash M : \tau \rrbracket : \llbracket \Gamma \rrbracket \rightarrow \llbracket \tau \rrbracket$$

$\llbracket x_1 : \sigma_1, \dots, x_n : \sigma_n \vdash x_i : \sigma_i \rrbracket := \pi_i \quad \text{for } i = 1 \dots n$  is Scott continuous.

$$\llbracket \Gamma \vdash \lambda x. M : \sigma \rightarrow \tau \rrbracket := \Lambda[\Gamma, x : \sigma \vdash M : \tau]$$

$$\llbracket \Gamma \vdash M N : \tau \rrbracket = \mathbf{ev} \circ \langle \llbracket \Gamma \vdash M : \sigma \rightarrow \tau \rrbracket, \llbracket \Gamma \vdash N : \sigma \rrbracket \rangle$$

$$\llbracket \Gamma \vdash \mathbf{zero} : \mathbf{nat} \rrbracket(\vec{d}) := 0$$

$$\llbracket \Gamma \vdash \mathbf{suc } M : \mathbf{nat} \rrbracket := S \circ \llbracket \Gamma \vdash M : \mathbf{nat} \rrbracket$$
